ENHANCED ARCHITECTURES OF VOLTAGE-CONTROLLED OSCILLATORS WITH SINGLE INDUCTOR (VCO-1L)

5

Technical field

The invention relates to voltage controlled oscillator circuits, and more particularly, to enhanced architectures of VCOs with a single inductor(VCO-1L).

10

Background art

All of today's wireless communication systems utilize voltage controlled oscillator (VCO) circuits. Among them are base stations and mobile terminals/mobile phones and current communication devices, such as radios, etc. Besides lower power consumption, higher output amplitudes, broader tuning range, and cleaner spectrum, a lower phase noise is a most important parameter. It is a major challenge for the designer of VCOs to optimize all the key parameters, especially enhanced phase noise, of a VCO.

20

The initial topology of a differential one-inductor VCO (VCO-1L) has been introduced in several publications and gained popularity mostly due the publication of Jan Craninckx and Michel S. J. Steyaert (A Fully Integrated CMOS DCS-1800 Frequency Synthesizer, IEEE Journal of Solid-State Circuits, Vol. 33, No.12, Dec.1998, pp. 2054-2065).

25

The main advantages of said initial topology are related to the simple high-gain architecture, which is operational on almost any Si-process where standard quality transistors having complimentary polarity are available.

30

Throughout the patent applications the same markers have been used(e.g. M1, M2, M3, etc) in the drawings and correspondent in this document to signify in an architectural sense identical components of the circuits shown..

5 A principal schematic of said circuit is presented in **Fig.1** prior art having a N-MOS current mirror **CM0** based on the N-MOS transistor **M0**, or, as shown in **Fig.2** prior art, with a P-MOS current mirror **CM01** based on the P-MOS transistor **M01**. The power supply is noted by V_{dd} and differential output can be taken from the single ended left-output **L** and right-output **R**. The principle of operation of
10 both variations is similar but the performance with respect to the frequency instability measured by phase-noise is not exactly the same.

As shown in **Fig.1** the N-MOS transistors **M1** and **M2** form the lower layer of the gain providing structure, while the P-MOS transistors **M3** and **M4** form the
15 upper layer. The parallel resonance LC-tank **L0-C0** is connected between said lower layer and said upper layer determining mainly the frequency of oscillation. Usually, but not limited to, the frequency of oscillation is controlled by some varactors which constitute the controllable part of the capacitance of the capacitor **C0**.

20

The circuit is oscillating in a cross-manner: when transistors **M1** and **M3** are heading toward opening up, the transistors **M2** and **M4** are going to a closing down.

25 While the current mirror **CM0** of **Fig. 1** prior art is built in N-MOS technology, the current mirror **CM01** of **Fig. 2** prior art is built using P-MOS technology. With the exception of the difference in the current mirrors **CM0** resp. **CM01** the structure of the circuits shown in **Fig. 1** prior art and in **Fig. 2** prior art is identical.

30

The timing of the process and indeed the stability of this timing are determined by the quality factor of the parallel resonance LC-tank formed by **L0** and **C0** in **Fig. 1** prior art and in **Fig. 2** prior art and the pick-to-pick amplitude

on it. Thus, the instability of the amplitude and the frequency are caused by the other components in the circuit, which compensate the energy losses in the tank in order to keep the oscillations continuous.

5 The current mirrors **CM0** resp. **CM01** shown in **Fig. 1** prior art resp. **Fig. 2** prior art provide current stabilization of the total differential current throughout the circuit.

10 Different design strategies are applied for those two versions shown in **Fig. 1** prior art and in **Fig.2** prior art of this topology, because the noise inside of the N-MOS and P-MOS transistors is different enough in nature and frequency components of said transistors, because the noise depends from the geometry and sizes of said transistors, and also because the major source of the noise in this architecture stems from the current mirrors **CM0** resp. **CM01**. Slight
15 preferences to the version with P-MOS mirror exist compared to the version with a N-MOS mirror.

 U. S. Patent 6,486,744 (to Cann) shows a low phase noise voltage-controlled oscillator (VCO) and method. The VCO comprises a negative resistance generator and a resonator that reduces VCO phase noise. In one
20 embodiment, the VCO comprises a negative resistance generator and a resonator structure that reduces VCO phase noise. The VCO uses the reflection properties of the resonator. An advantage of one embodiment of the VCO is its relatively low cost of manufacture compared to other VCOs. Another advantage of one embodiment of the VCO is its lower phase noise compared to conventional
25 microstrip resonators. In one embodiment, low phase noise performance is achieved by tuning the outside fingers of an interdigital filter resonator in the VCO and configuring suitable physical dimensions of the resonator. One aspect of the invention relates to a voltage-controlled oscillator comprising a resonator and a negative resistance generator. The resonator comprises a three-finger interdigital
30 filter and a plurality of varactors. A first varactor is coupled to a first finger of the interdigital filter and a ground terminal. A second varactor is coupled to a third finger of the interdigital filter and a ground terminal. A second finger of the

interdigital filter is coupled to a ground terminal. The first and second varactors are configured to alter a resonant frequency of the interdigital filter to a desired frequency in response to a tuning voltage applied to the resonator. The negative resistance generator is coupled to the resonator. The negative resistance generator is configured to receive a first signal with a particular frequency from the resonator. The negative resistance generator is configured to output a second signal with a substantially similar frequency and a higher amplitude compared to the first signal.

U. S. Patent 6,353,368 (to Iravani) discloses a low phase noise CMOS voltage controlled oscillator (VCO) circuit. The VCO circuit includes a bias circuit and a VCO cell coupled to the bias circuit. The VCO cell includes a VCO output for transmitting a VCO output signal. A frequency to voltage converter is coupled to receive the VCO output signal. The frequency to voltage converter converts a frequency of the VCO output signal into a corresponding voltage output. The voltage output is coupled to control the bias circuit. The VCO cell includes a current source coupled to the bias circuit such that the voltage output from the voltage a current converter provides negative feedback to the VCO cell via the current source. The negative feedback, in turn, reduces the phase noise on the VCO output signal.

U.S. Patent 6,181,216 (to Waight) discloses an oscillator using a Field-Effect Transistor (FET) in a Colpitts configuration. The circuit has a resistor from source to ground. Also connected to the source are two capacitors, one between the source and ground while the other is from source to gate. These capacitors provide a phase-shifted feedback signal to the gate. Also connected to the gate is a varactor tank, which has a voltage variable reactance that is used to tune the oscillation to the desired frequency. Between the drain of the FET and the supply voltage is a resistor-capacitor network. Between two series resistors a shunt capacitor is added to minimize local oscillator leakage onto the Vdd line. The resistor network also provides impedance for the Pre-Scalar output, which is simply a connection to the drain of the FET. The pre-scalar output is used to

provide a reference signal to the phase-locked loop, which generates the correction voltage to the oscillator's VCO input. It is at the pre-scalar output that a filter network is added to reduce the base-band noise from the Vdd line. By adding a shunt network, consisting of a small inductor and a low ESR capacitor, the supply noise is filtered without reducing the voltage or current supplied to the oscillator. The inductor removes the shunt capacitance at the oscillation frequency, avoiding any reduction in signal to the phase-locked loop circuit. The low ESR capacitor works with the resistance on-chip between the Vdd line and the drain to reduce the low frequency noise present at the FET's drain. This reduction in low-frequency noise results in improved phase noise performance without degrading any other circuit parameters:

Summary of the invention

A principal object of the present invention is to achieve topologies for voltage controlled oscillators with a single inductor having a low phase noise.

A further object of the present invention is to achieve topologies for voltage controlled oscillators with a single inductor having low power consumption.

Another further object of the present invention is to achieve topologies for voltage controlled oscillators with a single inductor having a broad tuning range.

In accordance with the objectives of this invention a circuit for a voltage controlled oscillator having a timing control by a bias circuitry and having a low phase-noise has been achieved. Said circuit comprises first a first pair of transistors being of a technology, wherein complementary polarity transistors are available, wherein the base of a first transistor of said pair is connected to the drain of a second transistor of said pair and the base of a second transistor of said pair is connected to the drain of said first transistor of said pair of transistors, the sources of said transistors are connected to each other and to a Vdd voltage,

and the drain of a first transistor of said first pair of transistors is connected to the drain of a first transistor of a second pair of transistors and the drain of a second transistor of said first pair of transistors is connected to the drain of a second transistor of said second pair of transistors, a power supply supplying said V_{dd} voltage, and a second pair of transistors being of a technology, wherein complementary polarity transistors are available, wherein the base of a first transistor of said second pair is connected via a means of a bias circuitry influencing timing control to the drain of a second transistor of said second pair and the base of a second transistor of said pair is connected via said means of a bias circuitry influencing timing control to the drain of said first transistor of said pair, each base is connected to said means of a bias circuitry influencing timing control, the sources of said pair of transistors are connected to each other and to a current source, and each drain of said transistors is connected to a means of a LC-tank. Furthermore said circuit comprises a means of a bias circuitry influencing timing control, a current mirror being connected to the sources of said second pair of transistors, a LC-tank being connected between the drains of said first pair of transistors, and a differential output comprising two ports being located at both sides of said LC-tank.

Also in accordance with the objectives of this invention a circuit for a voltage controlled oscillator having a timing control by a bias circuitry, a reduced power consumption, and a higher frequency stability and a low phase-noise has been achieved. Said circuit comprises a first pair of transistors, being of a technology wherein complementary polarity transistors are available, wherein the base of a first transistor of said pair is connected to the drain of a second transistor of said pair and the base of a second transistor of said pair is connected to the drain of said first transistor of said pair of transistors, the sources of said transistors are connected to each other and to a V_{dd} voltage, and the drain of a first transistor of said first pair of transistors is connected to the drain of a first transistor of a second pair of transistors and the drain of a second transistor of said first pair of transistors is connected to the drain of a second transistor of said second pair of transistors, a power supply supplying said V_{dd} voltage, and a second pair of transistors being of a technology wherein complementary polarity

transistors are available, wherein the base of a first transistor of said second pair is connected via a means of a bias circuitry influencing timing control to a means to introduce additional gain and the base of a second transistor of said pair is connected via said means of a bias circuitry influencing timing control to a means to introduce additional gain, each base is connected to said means of a bias circuitry influencing timing control, the sources of said pair of transistors are connected to each other and to a current source, and each drain of said transistors is connected to a means of a LC-tank, Furthermore said circuit comprises a means of a bias circuitry influencing timing control, a means to introduce additional gain in the amplification loop, a current mirror being connected to the sources of said second pair of transistors, a LC-tank being connected between the drains of said first pair of transistors, and a differential output comprising two ports being located at both sides of said LC-tank.

Also in accordance with the objectives of the invention a circuit for a voltage controlled oscillator being enabled for very low-power operations, having a low phase-noise, a timing control by a bias circuitry, a reduced power consumption, and a higher frequency stability has been achieved. Said circuit comprises a first pair of transistors being of a technology wherein complementary polarity transistors are available, wherein the base of a first transistor of said pair is connected to the drain of a second transistor of said pair and the base of a second transistor of said pair is connected to the drain of said first transistor of said pair of transistors, the sources of said transistors are connected to each other and to a Vdd voltage, and the drain of a first transistor of said first pair of transistors is connected to the drain of a first transistor of a second pair of transistors and the drain of a second transistor of said first pair of transistors is connected to the drain of a second transistor of said second pair of transistors, a power supply supplying said Vdd voltage, a second pair of transistors being of a technology wherein complementary polarity transistors are available, wherein the base of a first transistor of said second pair is connected via a means of a bias circuitry influencing timing control to a means to introduce additional gain and the base of a second transistor of said pair is connected via said means of a bias circuitry influencing timing control to a means to introduce additional gain, each

base is connected to said means of a bias circuitry influencing timing control, the sources of said pair of transistors are connected to each other and to a current source; and each drain of said transistors is connected to a means of a LC-tank. Furthermore said circuit comprises a means of a bias circuitry influencing timing control, a means to introduce additional gain in the amplification loop a means to actively discharge transistor channels, a current mirror being connected to the sources of said second pair of transistors, a LC-tank being connected between the drains of said first pair of transistors, and a differential output comprising two ports being located at both sides of said LC-tank.

10

Also in accordance with the objectives of the invention a circuit for a voltage controlled oscillator being enabled for very low current operations having a low phase-noise, a timing control by a bias circuitry, a reduced power consumption, a higher frequency stability, and an enlarged amplitude has been achieved. Said circuit comprises a first pair of transistors being of a technology, wherein complementary polarity transistors are available, wherein the base of a first transistor of said pair is connected to the drain of a second transistor of said pair and the base of a second transistor of said pair is connected to the drain of said first transistor of said pair of transistors, the sources of said transistors are connected to each other and to a V_{dd} voltage, and the drain of a first transistor of said first pair of transistors is connected to the drain of a first transistor of a second pair of transistors and the drain of a second transistor of said first pair of transistors is connected to the drain of a second transistor of said second pair of transistors, a power supply supplying said V_{dd} voltage, and a second pair of transistors being of a technology wherein complementary polarity transistors are available, wherein the base of a first transistor of said second pair is connected via a means of a bias circuitry influencing timing control to a means to introduce additional gain and the base of a second transistor of said pair is connected via said means of a bias circuitry influencing timing control to a means to introduce additional gain, each base is connected to said means of a bias circuitry influencing timing control, the sources of said pair of transistors are connected to each other and to a current source, and each drain of said transistors is connected to a means of a LC-tank. Furthermore said circuit comprises a means

of a bias circuitry influencing timing control, a means to introduce additional gain in the amplification loop, a means to enlarge the amplitude of the oscillations, a current mirror being connected to the sources of said second pair of transistors, a LC-tank being connected between the drains of said first pair of transistors, and a
5 differential output comprising two ports being located at both sides of said LC-tank.

Also in accordance with the objectives of the invention a circuit for a voltage controlled oscillator, being enabled for low current operation having
10 minimal power consumption, a very low phase-noise, a timing control by a bias circuitry, a higher frequency stability, and an enlarged amplitude has been achieved. Said circuit comprises a first pair of transistors, being of a technology wherein complementary polarity transistors are available, wherein the base of a first transistor of said pair is connected to the drain of a second transistor of said
15 pair and the base of a second transistor of said pair is connected to the drain of said first transistor of said pair of transistors, the sources of said transistors are connected to each other and to a V_{dd} voltage, and the drain of a first transistor of said first pair of transistors is connected to the drain of a first transistor of a second pair of transistors and the drain of a second transistor of said first pair of
20 transistors is connected to the drain of a second transistor of said second pair of transistors; a power supply supplying said V_{dd} voltage; a second pair of transistors being of a technology, wherein complementary polarity transistors are available, wherein the base of a first transistor of said second pair is connected via a means of a bias circuitry influencing timing control to a means to introduce
25 additional gain and the base of a second transistor of said pair is connected via said means of a bias circuitry influencing timing control to a means to introduce additional gain, each base is connected to said means of a bias circuitry influencing timing control, the sources of said pair of transistors are connected to each other and to a current source, and each drain of said transistors is
30 connected to a means of a LC-tank. Furthermore said circuit comprises a means of a bias circuitry influencing timing control, a means to run buffer-inverters in class C mode, a means to enlarge the amplitude of the oscillations, a current mirror being connected to the sources of said second pair of transistors, a LC-tank

being connected between the drains of said first pair of transistors, and a differential output comprising two ports being located at both sides of said LC-tank.

5 Description of the drawings

In the accompanying drawings, forming a material part of this description, there is shown:

Fig. 1 prior art shows an VCO-1L having a N-MOS current mirror

10 **Fig. 2 prior art** shows an VCO-1L having a P-MOS current mirror

Fig. 3 shows a timing control by bias circuitry of a VCO

Fig. 4 illustrates an active pull down circuit linked to a VCO.

Fig. 5 shows a N-MOS channel discharge by P-MOS linked to a VCO

Fig. 6 illustrates phase-noise tradeoffs by separate current mirrors of a VCO

15 **Fig. 7** illustrates a circuit of a VCO having an enlarged amplitude

Fig. 8 shows a circuit of a VCO having CMOS inverters instead of buffers

Fig. 9 illustrates a performance verification of the circuit using CMOS inverters

DESCRIPTION OF THE PREFERRED EMBODIMENTS

20

Disclosed are five different preferred embodiments of enhancements to prior art voltage controlled oscillators.

Fig.3 shows a circuit according to the present invention based on the referred prior art circuit as shown in **Fig. 1** prior art, characterized by means of an additional timing control 30. In the preferred embodiment shown in **Fig. 3** said additional timing control is

performed by capacitors **C1** and **C2**, resistors **R1** and **R2** and a threshold voltage **VG**. The capacitors remove the DC connection gate-drain of the cross coupled transistors and provide thus the possibility to set-time instances via the resistors when the transistors **M1** and **M2** will open and close. This depends of course from
5 the threshold voltage typical for the specific transistor in use, denoted usually by V_{th} or in case of bipolar transistors, this is the Shockley voltage, usually in the range of 0.6 to 0.9 Volts.

The rest of the structure of the circuit is without changes compared to the circuit shown in **Fig. 1** prior art comprising an N-MOS current mirror **CM0**, a lower layer
10 of the gain providing N-MOS structure **M1** and **M2**, an upper level of a gain providing P-MOS structure **M3** and **M4** and an LC-tank comprising the inductor **L0** and the capacitor **C0**.

There are more significant benefits for the circuit performance by the circuit
15 invented. Introducing the capacitors **C1** and **C2** also decreases the leakage of energy from the parallel resonance tank **Lo-Co**. Thus the capacitors used in said circuit should be of high quality, usually metal-insulator-metal (MIM) capacitors. Both capacitors have the same capacitance. The capacitance of said capacitors is determined by the desired frequency of the signal and is thus decreasing the
20 influence of low frequency noise from propagation in the amplifying loop of **M1** and **M2**.

The resistors **R1** and **R2** should be low-noise resistors because the noise generated by them is amplified in the gain-loop. Their resistance should be high
25 enough to prevent leakage of the energy of the LC-tank and low enough to generate not too much noise.

The value of the control voltage **VG** is set to provide the ability to shut-down the transistors as soon as the energy required to keep the oscillations in the
30 LC tank is secured. This provides also the ability to decrease the overall noise injected from those transistors, especially the $1/f$ noise, which is not generated, when the transistors are not in a conducting current state. With reference to the

quality factor of the tank, the shorter the time interval is while the transistors are open, the lower will be the injected noise, the lower will be the energy supplied to the LC-tank, and the higher will be the frequency stability of the circuit. All these positive characteristics can be achieved when the quality factor of the tank is high.

5

Thus, by introducing said bias circuitry the power consumption is reduced also and the circuit performance can be adjusted to the specifics of the silicon process used.

10

One of the properties of the circuit shown in Fig. 3 is that a especially higher gain of the transistors **M1-M2** is not required provided the quality factor of the resonance tank **L0-C0** is high enough. By reducing the gain the overall current consumption in the circuit can be decreased. On the other hand the gain needed at lower currents requires small in area transistors, which are having an higher 1/f

15

noise.

Same applies for the upper layer transistors **M3** and **M4** as shown in Fig. 3. Higher 1/f noise causes higher frequency instability, therefore it is desirable to increase the size of the transistors, which further decreases their gain. Also at smaller currents the amplitude of the generated signal is barely sufficient to maintain the control over the timing, thus further contributing to reduced frequency stability.

20

Fig. 4 shows a circuit according to the present invention introducing additional gain in the amplification loop and thus solving the inherent problems of the prior art circuits shown in Fig. 1 prior art, in Fig. 2 prior art and of the circuit invented shown in Fig. 3.

25

The number **40** signifies the means to introduce additional gain in the amplification loop. In the preferred embodiment shown in Fig. 4 said means comprises the transistors **M5-M7** and as well **M6-M8** forming source-follower type of buffers, i.e. current amplifiers. They inject the input current needed to re-charge the input capacitance of the main transistors **M2** and **M1** respectively, thus

30

providing additional gain in the loop. Their current mirrors **M7-based CM1** and **M8-based CM2** provide the small power required to keep **M5** and **M6** working only for a small fraction of the time-period when the main transistors **M1** and **M2** are on. To operate properly it is sufficient to have those transistors **M5** and **M6** very small in geometry. Therefore, they do not affect the performance of the LC-tank being connected to it.

The additional gain from **M5** and **M6** helps making the current in the core via the current mirror **CM01** smaller than in the original circuit shown in **Fig. 3**, thus decreasing the noise generated by this current mirror. At lower currents the transistors **M5** and **M6** still provide the gain needed to maintain the oscillations but load less the resonance tank **L0-C0**, which contributes further in frequency stability of the generated signal. And as additional benefit this architecture has potentially higher speed due to the smaller transistors in use, thus it can be used in broader and higher frequency range of applications.

Furthermore, the means **30** of additional timing control as shown in **Fig. 3** has been used in the circuit of **Fig. 4** as well.

Simulation runs demonstrate that the circuit shown in **Fig. 4** has a significant higher stability of frequency as the circuit shown in **Fig. 3** while the phase noise has the same order of magnitude in both circuits.

It is well known that for very low-power circuits the speed can be increased by actively pumping-out the charges of the channels of the MOS transistors by introducing additional complementary parallel conducting MOS transistors. This approach is classic for digital circuits and sampling circuits and it usually called transmission-gate.

The circuit shown in **Fig. 4** can be enhanced for enablement in very low-power operations in another embodiment of the present invention as shown in **Fig. 5**. Said enhancement is achieved by adding means **50** to actively discharge the transistor channels of the transistors **M1** and **M2** in order to increase the

speed of said transistors. In a preferred embodiment of the invention said means are comprising complementary transistors **M9** and **M10** in parallel with main transistors **M1** and **M2** respectively and additionally a pair of capacitors **C3** and **C4**.

5

Since the overall topology has a differential i.e. symmetrical structure, the signals for control the P-MOS transistors are immediately available and used as shown on **Fig. 5**. Adding those two transistors **M9** and **M10** has also the side benefits of improving the linearity of the switches **M1** and **M2** and further decreasing their serial resistance which contributes to decrease the requirements of the voltage power supply. Thus, the circuit shown in **Fig. 5** as part of the present invention is very suitable for applications requiring a low current power supply and a very low power consumption while having still a high speed/frequency of operation.

10

Furthermore the circuit shown in **Fig. 5** comprises the means of an additional timing control **30** as shown in **Fig. 3**, and said means to introduce additional gain in the amplification loop **40** as shown in **Fig. 4**.

15

The size of the transistors **M9** and **M10** is small and determined by the amount of accumulated charges in **M1** and **M2**. Thus, the capacitances of **M9** and **M10** are not reducing the speed of the overall circuit.

Simulation runs to simulate the phase noise of the circuit shown in **Fig. 5** demonstrate that the noise level, in spite of the low current operation, is still as good as the noise level achieved with the circuits shown in **Fig. 3** and in **Fig. 4**.

20

The circuit shown in **Fig.5** can be further enhanced. In case, the upper layer transistors have to operate in higher current densities, then discharging N-MOS transistors can be connected in parallel to them and the differential control signals are taken in the same manner from the structure.

25

An important control feature of the circuit is the ability to control the current of the current mirrors **CM1** and **CM2** independently from the main current mirror **CM0**. This provides opportunity for different trade-off between stability performance and current consumption, as illustrated on **Fig. 6**, showing the phase-noise trade-offs by separate currents in the current mirrors. The horizontal coordinate shows the frequency in the range from 100 KHz to 100 MHz, the vertical coordinate shows the centre phase noise in the range between -180 dBc/Hz and -100 dBc/Hz. There are three curves having as parameters currents of the current mirrors **CM1** and **CM2**. Curve **60** has got a current mirror in the magnitude of 0.5 mA, curve **61** has got a current mirror in the magnitude of 1mA, and curve **62** has got a current mirror in the magnitude of 1.5 mA. The increase of the current through **CM1** and **CM2** in the circuit of **Fig. 5**, provides better performance at higher frequency offset, which is in fact the case needed mostly for GSM, DCS/PCS and W-CDMA mobile terminals/phones.

The need to create a topology operational with a power supply having a further reduced voltage and still preserving the phase-noise performance at a given quality factor of the **L0-C0 tank** and given current consumption, leads to the need of enlarging the amplitude of the oscillations of the VCO. The analysis of the previous structures shows that the limitation of the amplitude is caused by the limit imposed by the voltage between the gate and drain of the upper layer transistors **M3** and **M4**, while this problem does not exist anymore after biasing circuitries have been introduced in lower layer transistors **M1** and **M2**.

Fig. 7 shows another embodiment of the present invention wherein the amplitude of the differential signal does not experience the limitation of the gate-drain voltage of the P-MOS transistors **M3** and **M4**. The circuit of **Fig. 7** comprises a means **70** to enlarge the amplitude of the oscillations. In a preferred embodiment of the present invention said means **70** to enlarge the amplitude of the oscillations comprises the resistors **R3** and **R4** and the capacitors **C3** and **C4**. The resistors **R3** and **R4**, added to the circuit shown in **Fig. 7**, release the gain from the direct control of the voltage over the **L0-C0 tank**, or in another words,

enables the voltage over the tank to be more independent from the limiting influence of the gate-drain voltage of the P-MOS transistors **M3** and **M4**.

In order to keep the regeneration process still active, i.e. the gain loop high enough to keep the oscillations going, small capacitors **C3** and **C4**, sustaining the oscillations, are added to the circuit shown in **Fig. 7** located parallel to the resistors **R3** and **R4**. Since they are parallel to the resonance tank too, they have to be high quality factor capacitors, similar to type of **C1** and **C2**. Those capacitors, sustaining the oscillations, would not be enough to keep the circuit operational if the additional gain of the buffers **M5** and **M6** was not introduced in the circuit. The resulting amplitude of the circuit shown in **Fig. 7** is about twice as high as the amplitude of the circuits shown in **Figs 3, 4** and **5**. Additionally and in fact as the primary objective the phase noise performance is absolutely better compared to the circuits shown in **Figs 3, 4** and **5**.

15

Furthermore the circuit shown in **Fig. 7** comprises the means of an additional timing control **30** as shown in **Fig. 3**, and said means to introduce additional gain in the amplification loop **40** as shown in **Fig. 4**.

20

Additionally the circuit shown in **Fig. 7** offers much more flexibility to the designer of the circuit. The upper layer of the circuit shown in **Fig. 4**, comprising the transistors **M3** and **M4**, and the lower layer of the circuit, comprising the transistors **M1** and **M2**, can be designed independently to establish the gain required in the two loops.

25

The requirement to decrease still further the power consumption and still to preserve the performance of the circuit topology leads to the use of means **80** to run buffer-inverter in class-C mode. A preferred embodiment of the present invention is shown in **Fig.8**. C-MOS inverters-buffers are used in the gain loop. Said means **80** to run buffer-inverter in class-C mode comprises the transistors **M9** to **M16** in a preferred embodiment of the invention.

30

The signals from the **L0-C0 tank** are amplified and inverted by two pairs of CMOS transistors **M10/M11** and **M14/M15**, while transistors **M9**, **M12**, **M13** and **M16** serve as current biasing components. By said transistors **M9**, **M12**, **M13** and **M16** it is possible to tune the CMOS buffers-inverters to work in deep class-C mode, which is energy saving and is a low-noise circuitry by nature, thus a better performance of the circuit topology is achieved. Class-C mode is a mode of operation of transistor amplifier which is characterized by only a small portion of the input signal is present in the output signal. Since the transistor does not conduct except during a small portion of the input signal, this is the most efficient amplifier. Since there is already inversion on the way due to the CMOS pairs, the output of each buffer is applied to the corresponding transistors in the nearest branch.

Furthermore, there is no need of current mirrors to control the current through the buffers, it is done automatically done having an adequate design of the bias transistors **M9**, **M12**, **M13** and **M16**. The higher output amplitude achieved by the circuit shown in **Fig. 8** is also important when the VCO is to be used in transmitter circuitries wherein higher output power is required, for example in GSM, PCS/DCS, W-CDMA etc. applications.

Furthermore the circuit shown in **Fig. 8** comprises the means of an additional timing control **30** as shown in **Fig. 3**, and said means to enlarge the amplitude of the oscillations **70** as shown in **Fig. 7**.

Fig. 9 shows simulation results of the circuit shown in **Fig. 8**. The horizontal coordinate shows the offset from the oscillating frequency, which is from 10 KHz to 50 MHz, the vertical coordinate shows the centre phase noise in the range between -180 dBc/Hz and -80 dBc/Hz. The centre phase noise in the five operating points **m1** to **m5** ranges between -164.6 dBc in the operating point **m1**, having an offset of 50 Mhz, to -92.25 dBc in the operating point **m5**, having an offset of 10 Khz. It has to be noted that the amplitudes at the buffer input and output are very high.

Claims

1. A circuit for a voltage controlled oscillator having a timing control by a bias circuitry and having a low phase-noise comprising:

- 5 - a first pair of transistors being of a technology wherein complementary polarity transistors are available, wherein the base of a first transistor of said pair is connected to the drain of a second transistor of said pair and the base of a second transistor of said pair is connected to the drain of said first transistor of said pair of transistors, the sources of said transistors are connected to each other and to a Vdd voltage, and the drain of a first transistor of said first pair of transistors is connected to the drain of a first transistor of a second pair of transistors and the drain of a second transistor of said first pair of transistors is connected to the drain of a second transistor of said second pair of transistors;
10 - a power supply supplying said Vdd voltage;
- 15 - a second pair of transistors being of a technology wherein complementary polarity transistors are available, wherein the base of a first transistor of said second pair is connected via a means of a bias circuitry influencing timing control to the drain of a second transistor of said second pair and the base of a second transistor of said pair is connected via said means of a bias circuitry influencing
20 timing control to the drain of said first transistor of said pair, each base is connected to said means of a bias circuitry influencing timing control, the sources of said pair of transistors are connected to each other and to a current source, and each drain of said transistors is connected to a means of a LC-tank;
25 - a means of a bias circuitry influencing timing control;
- 25 - a current mirror being connected to the sources of said second pair of transistors;
- a LC-tank being connected between the drains of said first pair of transistors;
and

- a differential output comprising two ports being located at both sides of said LC-tank.

2. The circuit of claim 1 wherein said first and second pair of transistors are either MOS, BiCMOS, GaAs or bipolar transistors.

5 3. A circuit for a voltage controlled oscillator having a timing control by a bias circuitry, a reduced power consumption, and a higher frequency stability and a low phase-noise comprising:

10 - a first pair of transistors being of a technology wherein complementary polarity transistors are available, wherein the base of a first transistor of said pair is connected to the drain of a second transistor of said pair and the base of a second transistor of said pair is connected to the drain of said first transistor of said pair of transistors, the sources of said transistors are connected to each other and to a Vdd voltage, and the drain of a first transistor of said first pair of transistors is connected to the drain of a first transistor of a second pair of transistors and the drain of a second transistor of said first pair of transistors is connected to the drain of a second transistor of said second pair of transistors;

- a power supply supplying said Vdd voltage;

20 - a second pair of transistors being of a technology wherein complementary polarity transistors are available, wherein the base of a first transistor of said second pair is connected via a means of a bias circuitry influencing timing control to a means to introduce additional gain and the base of a second transistor of said pair is connected via said means of a bias circuitry influencing timing control to a means to introduce additional gain, each base is connected to said means of a bias circuitry influencing timing control, the sources of said pair of transistors are connected to each other and to a current source, and each drain of said transistors is connected to a means of a LC-tank;

- a means of a bias circuitry influencing timing control;

- a means to introduce additional gain in the amplification loop;

- a current mirror being connected to the sources of said second pair of transistors;

- a LC-tank being connected between the drains of said first pair of transistors;
- and

5 - a differential output comprising two ports being located at both sides of said LC-tank.

4. The circuit of claim 3 wherein said four pairs of transistors are either MOS or BiCMOS or GaAs or bipolar transistors.

10 5. The circuit of claim 3 wherein said means to introduce additional gain in the amplification loops of the VCO is comprising current amplifiers and related current mirrors.

15 6. The circuit of claim 5 where in said means to introduce additional gain comprise a third and a fourth additional pairs of transistors of a source-follower type of buffers, wherein the sources of both first transistors of said third and fourth pairs are connected to ground, the bases of both first transistors are part of a current mirror each and the drains of said first transistor are each connected to one of the sources of the second transistors of said third and fourth pairs of transistors and to said means of a bias circuitry, the base of said second transistor of said third pair is connected to the drain of the first transistor of said first pair of transistors
20 and the base of the second transistor of the fourth pair is connected to the drain of the second transistor of said first pair of transistors and the drains of said second transistors of said third and fourth pair are both connected to Vdd voltage.

25 7. A circuit for a voltage controlled oscillator being enabled for very low-power operations having a low phase-noise, a timing control by a bias circuitry, a reduced power consumption, and a higher frequency stability comprising:

- a first pair of transistors being of a technology wherein complementary polarity transistors are available, wherein the base of a first transistor of said pair is connected to the drain of a second transistor of said pair and the base of a second transistor of said pair is connected to the drain of said first transistor of

said pair of transistors, the sources of said transistors are connected to each other and to a Vdd voltage, and the drain of a first transistor of said first pair of transistors is connected to the drain of a first transistor of a second pair of transistors and the drain of a second transistor of said first pair of transistors is
5 connected to the drain of a second transistor of said second pair of transistors;

- a power supply supplying said Vdd voltage;

- a second pair of transistors being of a technology wherein complementary polarity transistors are available, wherein the base of a first transistor of said second pair is connected via a means of a bias circuitry influencing timing control
10 to a means to introduce additional gain and the base of a second transistor of said pair is connected via said means of a bias circuitry influencing timing control to a means to introduce additional gain, each base is connected to said means of a bias circuitry influencing timing control, the sources of said pair of transistors are connected to each other and to a current source, and each drain of said
15 transistors is connected to a means of a LC-tank;

- a means of a bias circuitry influencing timing control;

- a means to introduce additional gain in the amplification loop;

- a means to actively discharge transistor channels;

- a current mirror being connected to the sources of said second pair of
20 transistors;

- a LC-tank being connected between the drains of said first pair of transistors;
and

- a differential output comprising two ports being located at both sides of said LC-tank.

25

8. The circuit of claim 7 wherein said means to actively discharge transistor channels is comprising complementary conducting transistors and capacitors.

9. The circuit of claim 8 wherein said means to actively discharge transistor channels is comprising:

5 - a first transistor, wherein the source of said transistor is connected to the drain of the first transistor of said second pair of transistors, the drain of said transistor is connected to the source of said first transistor and the base is connected to a first side of a first capacitor;

10 - a second transistor, wherein the source of said transistor is connected to the drain of the second first transistor of said second pair of transistors, the drain of said transistor is connected to the source of said second transistor and the base is connected to a first side of a second capacitor;

- a first capacitor, wherein its first side is connected to the base of said first transistor and its second side is connected to said means to introduce additional gain in the amplification loop; and

15 - a second capacitor, wherein its first side is connected to the base of said second transistor and its second side is connected to said means to introduce additional gain in the amplification loop.

20 10. The circuit of claim 9 wherein the second side of said first capacitor is connected to the drain of said first transistor of said third pair of transistors and wherein the second side of said second capacitor is connected to the drain of said first transistor of said fourth pair of transistors.

25 11. A circuit for a voltage controlled oscillator being enabled for very low current operations having a low phase-noise, a timing control by a bias circuitry, a reduced power consumption, a higher frequency stability, and an enlarged amplitude comprising:

- a first pair of transistors being of a technology wherein complementary polarity transistors are available, wherein the base of a first transistor of said pair is connected to the drain of a second transistor of said pair and the base of a second transistor of said pair is connected to the drain of said first transistor of said pair of transistors, the sources of said transistors are connected to each other and to a Vdd voltage, and the drain of a first transistor of said first pair of transistors is connected to the drain of a first transistor of a second pair of transistors and the drain of a second transistor of said first pair of transistors is connected to the drain of a second transistor of said second pair of transistors;
- 10 - a power supply supplying said Vdd voltage;
- a second pair of transistors being of a technology wherein complementary polarity transistors are available, wherein the base of a first transistor of said second pair is connected via a means of a bias circuitry influencing timing control to a means to introduce additional gain and the base of a second transistor of said pair is connected via said means of a bias circuitry influencing timing control to a means to introduce additional gain, each base is connected to said means of a bias circuitry influencing timing control, the sources of said pair of transistors are connected to each other and to a current source, and each drain of said transistors is connected to a means of a LC-tank;
- 20 - a means of a bias circuitry influencing timing control;
- a means to introduce additional gain in the amplification loop;
- a means to enlarge the amplitude of the oscillations;
- a current mirror being connected to the sources of said second pair of transistors;
- 25 - a LC-tank being connected between the drains of said first pair of transistors; and
- a differential output comprising two ports being located at both sides of said LC-tank.

12. The circuit of anyone of claims 1 , 3, 7 and 11 wherein said means of a bias circuitry is comprising a combination of capacitors and resistors and a voltage source providing a threshold voltage.

5

13. The circuit of claim 12 wherein said means of a bias circuitry comprises two capacitors and two resistors and a threshold voltage source, wherein one capacitors is connected between the drain of a first transistor of said second pair of transistors and the base of a second transistor of said second pair and the
10 other capacitor is connected between the drain of a second transistor of said second pair of transistors and the base of a first transistor of said second pair and one of both said resistors is connected on one side to the base of the first transistor of said second pair and the other resistor is connected on one side to the base of the other transistor of the second pair and both resistors are
15 connected to said threshold voltage source on their other sides. wherein said means of a bias circuitry is comprising a combination of capacitors and resistors and a voltage source providing a threshold voltage.

14. The circuit of claim 13 wherein said capacitors are a high quality capacitors.

20

15. The circuit of claim 14 wherein said high quality capacitors are metal-insulator-metal (MIM) capacitors.

16. The circuit of claim 13 wherein said resistors are low-noise resistors.

25

17. A circuit for a voltage controlled oscillator being enabled for low current operation having minimal power consumption, a very low phase-noise, a timing

control by a bias circuitry, a higher frequency stability, and an enlarged amplitude comprising:

- a first pair of transistors being of a technology wherein complementary polarity transistors are available, wherein the base of a first transistor of said pair is connected to the drain of a second transistor of said pair and the base of a second transistor of said pair is connected to the drain of said first transistor of said pair of transistors, the sources of said transistors are connected to each other and to a Vdd voltage, and the drain of a first transistor of said first pair of transistors is connected to the drain of a first transistor of a second pair of transistors and the drain of a second transistor of said first pair of transistors is connected to the drain of a second transistor of said second pair of transistors;
- a power supply supplying said Vdd voltage;
- a second pair of transistors being of a technology wherein complementary polarity transistors are available, wherein the base of a first transistor of said second pair is connected via a means of a bias circuitry influencing timing control to a means to introduce additional gain and the base of a second transistor of said pair is connected via said means of a bias circuitry influencing timing control to a means to introduce additional gain, each base is connected to said means of a bias circuitry influencing timing control, the sources of said pair of transistors are connected to each other and to a current source, and each drain of said transistors is connected to a means of a LC-tank;
- a means of a bias circuitry influencing timing control;
- a means to run buffer-inverters in class C mode;
- a means to enlarge the amplitude of the oscillations;
- a current mirror being connected to the sources of said second pair of transistors;
- a LC-tank being connected between the drains of said first pair of transistors; and

- a differential output comprising two ports being located at both sides of said LC-tank.

18. The circuit of claim 17 wherein said means of a bias circuitry is comprising a combination of capacitors and resistors and a voltage source providing a threshold voltage.

19. The circuit of claim 18 wherein said means of a bias circuitry comprises two capacitors and two resistors and a threshold voltage source, wherein one capacitor is connected between said means to run buffer-inverters in class C mode and the base of a second transistor of said second pair and the other capacitor is connected between said means to run buffer-inverters in class C mode and the base of a first transistor of said second pair and one of both said resistors is connected on one side to the base of the first transistor of said second pair and the other resistor is connected on one side to the base of the other transistor of the second pair and both resistors are connected to said threshold voltage source on their other sides. wherein said means of a bias circuitry is comprising a combination of capacitors and resistors and a voltage source providing a threshold voltage.

20

20. The circuit of claim 19 wherein said capacitors are a high quality capacitors.

21. The circuit of claim 20 wherein said high quality capacitor is a metal-insulator-metal (MIM) capacitor.

25

22. The circuit of claim 18 wherein said resistors are low-noise resistors.

23. The circuit of anyone of claims 1, 3, 7 or 12 wherein said means of a LC-tank comprises an inductor having a means of providing capacitance parallel connected.

5 24. The circuit of claim 23 wherein said means of providing capacitance comprises a variable capacitor (varactor).

25. The circuit of claim 7, 11 or 17 wherein all transistors are either MOS, BiCMOS, GaAs or bipolar transistors.

10

26. The circuit of claim 17 wherein said means to enlarge the amplitude of the oscillations is comprising an arrangement of resistors and capacitors.

15 27. The circuit of claim 26 wherein said arrangement of resistors and capacitors is comprising two pairs of a resistor and a capacitor connected in parallel each wherein the first pair of a resistor and a capacitor is connected between the drain of the first transistor of said first pair of transistors and the base of the second transistor of said first pair and the second pair of a resistor and a capacitor is connected between the drain of the second transistor and the base of the first
20 transistor of said first pair of transistors.

28. The circuit of claim 17 wherein said means to run buffer-inverters in class C mode is comprising transistors amplifying and inverting the signals while other transistors are providing biasing currents.

25

29. The circuit of claim 28 wherein said means to run buffer inverters in class C mode comprise two lines of concatenated transistors, wherein the first line of concatenated transistors comprises:

5 - a first transistor, wherein the gate and the drain is connected to Vdd voltage and the source is connected to the source of a second transistor;

- a second transistor, wherein the gate is connected to a first leg of said LC-tank and to the base of a third transistor and the drain is connected to the drain of a third transistor and to said means of bias circuitry;

10 - a third transistor, wherein the source is connected to the drain and to the gate of a fourth transistor; and

- a fourth transistor, wherein the source is connected to ground;

and wherein the second line of concatenated transistors comprises:

- a first transistor, wherein the gate and the drain is connected to Vdd voltage and the source is connected to the source of a second transistor;

15 - a second transistor, wherein the gate is connected to a second leg of said LC-tank and to the base of a third transistor and the drain is connected to the drain of a third transistor and to said means of bias circuitry;

- a third transistor, wherein the source is connected to the drain and to the gate of a fourth transistor; and

20 - a fourth transistor, wherein the source is connected to ground.

30. The circuit of claim 29 wherein the connection between the drain of the second transistor of said first line of transistors to said means of bias circuitry is performed via the capacitor being connected to the gate of the first transistor of said second pair of transistors and the connection between the drain of the second transistor of said second line of transistors to said means of bias circuitry is performed via the capacitor being connected to the gate of the second transistor of said second pair of transistors.

ABSTRACT

Five circuit topologies of Voltage-Controlled Oscillators with Single Inductor (VCO-1L) are proposed. They offer lower power consumption, higher output amplitude; broader tuning range, cleaner spectrum and higher frequency stability seen as lower phase-noise. Most of the achievements are based on the development of active pull-down control circuitries of the timing and active charge dissipation in the transistors. The applications of the present invention are of critical importance for wireless communication systems not allowing any limitations in the frequency range. Among them are base stations and mobile terminals/mobile phones, GSM, PCS/DCS, W-CDMA etc., as well BlueTooth, Wireless LAN, Automotive and ISM band etc. The advanced performance of the circuits is based on important architectural specifics and proven by simulation on advanced CMOS process. The architectures are not limited to use on CMOS; they can be efficiently used in any semiconductor process where complimentary polarity transistors are available, for example BiCMOS, SiGe/BiCMOS, GaAs etc.
